AR: autoregressive (lagged observations as inputs)

I: integrated (differencing to make series stationary)

MA: moving average (lagged errors as inputs)

AR: autoregressive (lagged observations as inputs)

I: integrated (differencing to make series stationary)

MA: moving average (lagged errors as inputs)

An ARIMA model is rarely interpretable in terms of visible data structures like trend and seasonality. But it can capture a huge range of time series patterns.

Stationarity

Definition

If $\{y_t\}$ is a stationary time series, then for all s, the distribution of (y_t, \ldots, y_{t+s}) does not depend on t.

Stationarity

Definition

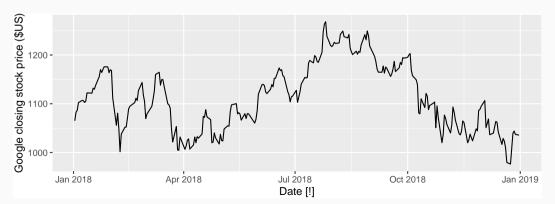

If $\{y_t\}$ is a stationary time series, then for all s, the distribution of (y_t, \ldots, y_{t+s}) does not depend on t.

A **stationary series** is:

- roughly horizontal
- constant variance
- no patterns predictable in the long-term

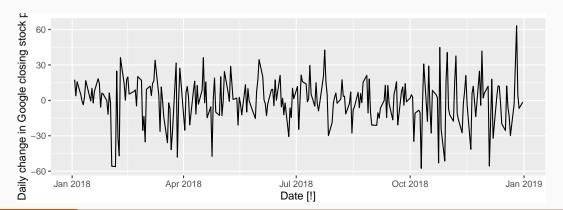

Stationary?

```
gafa_stock ▷
filter(Symbol = "G00G", year(Date) = 2018) ▷
autoplot(Close) +
ylab("Google closing stock price ($US)")
```

Stationary?

```
gafa_stock ▷
  filter(Symbol = "G00G", year(Date) = 2018) ▷
  autoplot(difference(Close)) +
  ylab("Daily change in Google closing stock price")
```

Differencing

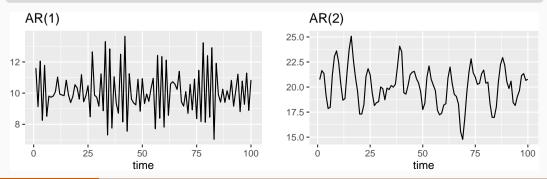

- Differencing helps to **stabilize the mean**.
- The differenced series is the *change* between each observation in the original series.
- Occasionally the differenced data will not appear stationary and it may be necessary to difference the data a second time.
- In practice, it is almost never necessary to go beyond second-order differences.

Autoregressive models

Autoregressive (AR) models:

$$y_t = c + \phi_1 y_{t-1} + \phi_2 y_{t-2} + \cdots + \phi_p y_{t-p} + \varepsilon_t,$$

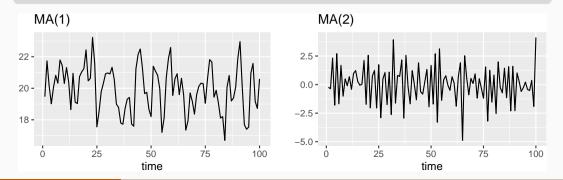

where ε_t is white noise. A multiple regression with **lagged values** of y_t as predictors.

Moving Average (MA) models

Moving Average (MA) models:

 $y_t = c + \varepsilon_t + \theta_1 \varepsilon_{t-1} + \theta_2 \varepsilon_{t-2} + \cdots + \theta_q \varepsilon_{t-q},$ where ε_t is white noise. A multiple regression with **lagged** errors as predictors. Don't confuse with moving average smoothing!

Autoregressive Moving Average models:

$$y_{t} = c + \phi_{1}y_{t-1} + \dots + \phi_{p}y_{t-p} + \theta_{1}\varepsilon_{t-1} + \dots + \theta_{q}\varepsilon_{t-q} + \varepsilon_{t}.$$

Autoregressive Moving Average models:

$$y_{t} = c + \phi_{1}y_{t-1} + \dots + \phi_{p}y_{t-p} + \theta_{1}\varepsilon_{t-1} + \dots + \theta_{q}\varepsilon_{t-q} + \varepsilon_{t}.$$

Predictors include both lagged values of y_t and lagged errors.

Autoregressive Moving Average models:

$$y_{t} = c + \phi_{1}y_{t-1} + \dots + \phi_{p}y_{t-p} + \theta_{1}\varepsilon_{t-1} + \dots + \theta_{q}\varepsilon_{t-q} + \varepsilon_{t}.$$

Predictors include both lagged values of y_t and lagged errors.

Autoregressive Integrated Moving Average models

- Combine ARMA model with **differencing**.
- *d*-differenced series follows an ARMA model.
- Need to choose p, d, q and whether or not to include c.

ARIMA(p, d, q) model

- AR: p =order of the autoregressive part
 - I: d =degree of first differencing involved
- MA: q =order of the moving average part.
 - White noise model: ARIMA(0,0,0)
 - Random walk: ARIMA(0,1,0) with no constant
 - Random walk with drift: ARIMA(0,1,0) with const.
 - \blacksquare AR(p): ARIMA(p,0,0)
 - \blacksquare MA(q): ARIMA(0,0,q)

```

Understanding ARIMA models

- If c = 0 and d = 0, the long-term forecasts will go to zero.
- If c = 0 and d = 1, the long-term forecasts will go to a non-zero constant.
- If c = 0 and d = 2, the long-term forecasts will follow a straight line.
- If $c \neq 0$ and d = 0, the long-term forecasts will go to the mean of the data.
- If $c \neq 0$ and d = 1, the long-term forecasts will follow a straight line.
- If $c \neq 0$ and d = 2, the long-term forecasts will follow a quadratic trend.

Understanding ARIMA models

Forecast variance and *d*

- The higher the value of *d*, the more rapidly the prediction intervals increase in size.
- For d = 0, the long-term forecast standard deviation will go to the standard deviation of the historical data.

Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences *d* via KPSS test.
- Select *p*, *q* and inclusion of *c* by minimising AICc.
- Use stepwise search to traverse model space.

Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- Select p, q and inclusion of c by minimising AICc.
- Use stepwise search to traverse model space.

AICc =
$$-2\log(L) + 2(p+q+k+1)\left[1 + \frac{(p+q+k+2)}{T-p-q-k-2}\right]$$
.

where *L* is the maximised likelihood fitted to the *differenced* data, k = 1 if $c \neq 0$ and k = 0 otherwise.

Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- Select p, q and inclusion of c by minimising AICc.
- Use stepwise search to traverse model space.

AICc =
$$-2\log(L) + 2(p+q+k+1)\left[1 + \frac{(p+q+k+2)}{T-p-q-k-2}\right]$$
.

where *L* is the maximised likelihood fitted to the *differenced* data, k = 1 if $c \neq 0$ and k = 0 otherwise.

Note: Can't compare AICc for different values of d.

Step1: Select current model (with smallest AICc) from:

ARIMA(2, d, 2)

ARIMA(0, d, 0)

ARIMA(1, d, 0)

ARIMA(0, d, 1)

- **Step 2:** Consider variations of current model:
 - vary one of p, q, from current model by ± 1 ;
 - p, q both vary from current model by ± 1 ;
 - Include/exclude *c* from current model.

Model with lowest AICc becomes current model.

```
Step1: Select current model (with smallest AICc) from:
```

ARIMA(2, d, 2)

ARIMA(0, d, 0)

ARIMA(1, d, 0)

ARIMA(0, d, 1)

Step 2: Consider variations of current model:

- vary one of p, q, from current model by ± 1 ;
- p, q both vary from current model by ± 1 ;
- Include/exclude *c* from current model.

Model with lowest AICc becomes current model.

Repeat Step 2 until no lower AICc can be found.

Outline

- 4 Lab Session 17
- 5 Forecast ensembles

Lab Session 16

For the United States GDP data (from global_economy):

- Fit a suitable ARIMA model for the logged data.
- Produce forecasts of your fitted model. Do the forecasts look reasonable?

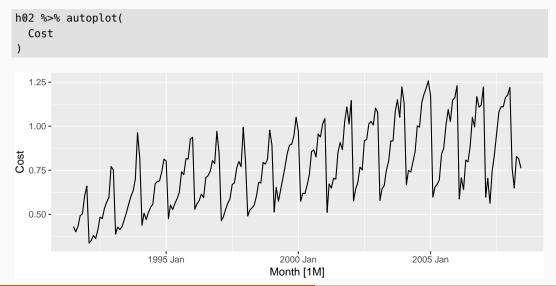

Outline

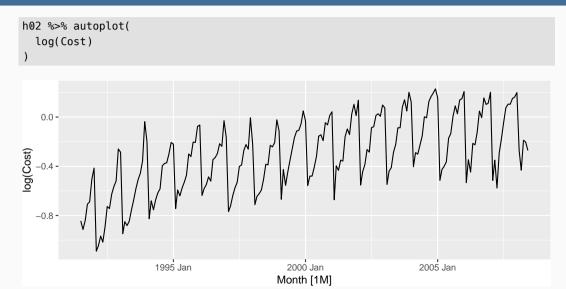

- 1 ARIMA models
- 2 Lab Session 16
- 3 Seasonal ARIMA models
- 4 Lab Session 17

```
h02 <- PBS %>%

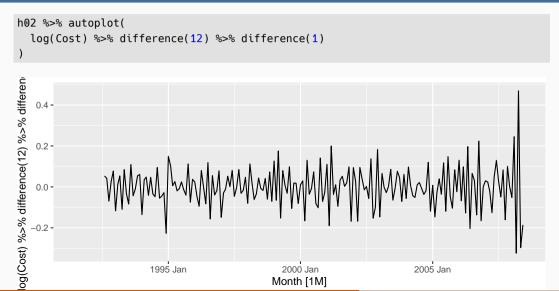

filter(ATC2 = "H02") %>%

summarise(Cost = sum(Cost)/1e6)
```

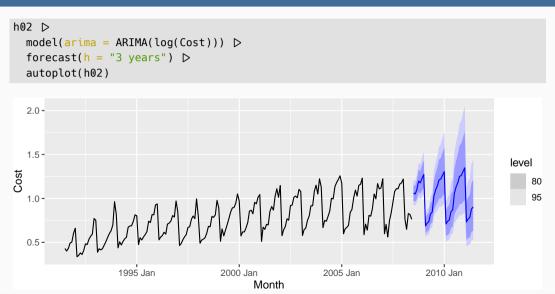

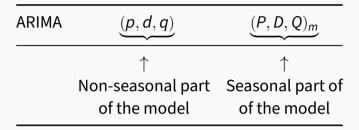

Example: US electricity production

```
h02 ⊳
 model(arima = ARIMA(log(Cost))) ▷
 report()
## Series: Cost
## Model: ARIMA(2,1,0)(0,1,1)[12]
## Transformation: log(Cost)
##
## Coefficients:
                     ar2 sma1
###
            ar1
##
       -0.8491 -0.4207 -0.6401
## s.e. 0.0712 0.0714 0.0694
##
## sigma^2 estimated as 0.004387: log likelihood=245
## ATC=-483 ATCc=-483 BTC=-470
```

Example: US electricity production

Seasonal ARIMA models

- \blacksquare m = number of observations per year.
- *d* first differences, *D* seasonal differences
- p AR lags, q MA lags
- P seasonal AR lags, Q seasonal MA lags

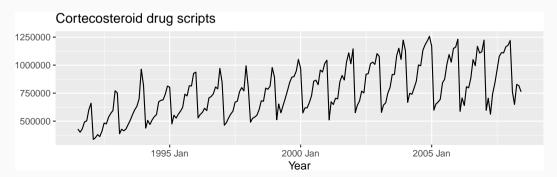

Seasonal and non-seasonal terms combine multiplicatively

Common ARIMA models

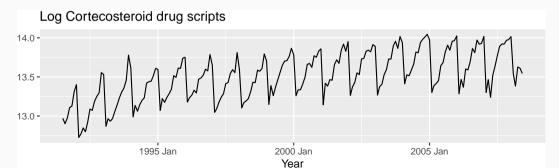

The US Census Bureau uses the following models most often:

$ARIMA(0,1,1)(0,1,1)_m$	with log transformation
$ARIMA(0,1,2)(0,1,1)_m$	with log transformation
$ARIMA(2,1,0)(0,1,1)_m$	with log transformation
$ARIMA(0,2,2)(0,1,1)_m$	with log transformation
$ARIMA(2,1,2)(0,1,1)_m$	with no transformation

- 3 Seasonal ARIMA models
- 4 Lab Session 17
- 5 Forecast ensembles

Lab Session 17

For the Australian tourism data (from tourism):

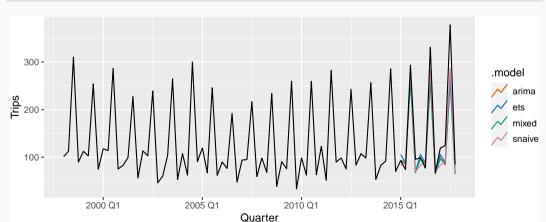

- Fit a suitable ARIMA model for all data.
- Produce forecasts of your fitted models.
- Check the forecasts for the "Snowy Mountains" and "Melbourne" regions. Do they look reasonable?

Outline

- 1 ARIMA models
- 2 Lab Session 16
- 3 Seasonal ARIMA models
- 4 Lab Session 17
- 5 Forecast ensembles

- Ensemble forecast mixed is a simple average of the three fitted models.
- forecast() will produce distributional forecasts taking into account the correlations between the forecast errors of the component models.

```
fc <- fit ▷ forecast(h = "3 years")
fc ▷ filter(Region = "Snowy Mountains", Purpose = "Holiday") ▷
  autoplot(tourism, level = NULL)</pre>
```

```
accuracy(fc, tourism)  
  group_by(.model)  
  summarise(
    RMSE = mean(RMSE),
    MAE = mean(MAE),
    MASE = mean(MASE)
)  
  arrange(RMSE)
```

```

Can we do better than equal weights?

Can we do better than equal weights?

- Hard to find weights that improve forecast accuracy.
- Known as the "forecast combination puzzle".
- Solution: FFORMA

Can we do better than equal weights?

- Hard to find weights that improve forecast accuracy.
- Known as the "forecast combination puzzle".
- Solution: FFORMA

FFORMA (Feature-based FORecast Model Averaging)

- Vector of time series features used to predict best weights.
- A modification of xgboost is used.
- Method came 2nd in the 2018 M4 international forecasting competition.
- Main author: Pablo Montero-Manso (Monash U)
- Not (yet) available for fable.
