- 6 Lab Session 15
  - 7 Non-Gaussian forecast distributions

## The Pharmaceutical Benefits Scheme (PBS) is the Australian government drugs subsidy scheme.

- Many drugs bought from pharmacies are subsidised to allow more equitable access to modern drugs.
- The cost to government is determined by the number and types of drugs purchased. Currently nearly 1% of GDP.
- The total cost is budgeted based on forecasts of drug usage.

**Federal Election** 

- In 2001: \$4.5 billion budget, under-forecasted by \$800 million.
- Thousands of products. Seasonal demand.
- Subject to covert marketing, volatile products, uncontrollable expenditure.
- Although monthly data available for 10 years, data are aggregated to annual values, and only the first three years are used in estimating the forecasts.
- All forecasts being done with the FORECAST function in MS-Excel!

## **Historical perspective**

- Developed in the 1950s and 1960s as methods (algorithms) to produce point forecasts.
- Combine a "level", "trend" (slope) and "seasonal" component to describe a time series.
- The rate of change of the components are controlled by "smoothing parameters":  $\alpha$ ,  $\beta$  and  $\gamma$  respectively.
- Need to choose best values for the smoothing parameters (and initial states).
- Equivalent ETS state space models developed in the 1990s and 2000s.

We want a model that captures the level  $(\ell_t)$ , trend  $(b_t)$  and seasonality  $(s_t)$ .

How do we combine these elements?

We want a model that captures the level  $(\ell_t)$ , trend  $(b_t)$  and seasonality  $(s_t)$ .

#### How do we combine these elements?

#### **Additively?**

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

We want a model that captures the level  $(\ell_t)$ , trend  $(b_t)$  and seasonality  $(s_t)$ .

#### How do we combine these elements?

#### **Additively?**

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

## **Multiplicatively?**

$$y_t = \ell_{t-1}b_{t-1}s_{t-m}(1+\varepsilon_t)$$

We want a model that captures the level  $(\ell_t)$ , trend  $(b_t)$  and seasonality  $(s_t)$ .

#### How do we combine these elements?

#### **Additively?**

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

## **Multiplicatively?**

$$y_t = \ell_{t-1}b_{t-1}s_{t-m}(1+\varepsilon_t)$$

#### Perhaps a mix of both?

$$y_t = (\ell_{t-1} + b_{t-1})s_{t-m} + \varepsilon_t$$

We want a model that captures the level  $(\ell_t)$ , trend  $(b_t)$  and seasonality  $(s_t)$ .

#### How do we combine these elements?

#### **Additively?**

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

#### Multiplicatively?

$$y_t = \ell_{t-1}b_{t-1}s_{t-m}(1+\varepsilon_t)$$

#### Perhaps a mix of both?

$$\mathbf{v}_t = (\ell_{t-1} + b_{t-1})\mathbf{s}_{t-m} + \varepsilon_t$$

How do the level, trend and seasonal components evolve over time?

#### **ETS models**

```
General notation ETS: ExponenTial Smoothing

→ ↑ 

Error Trend Season
```

**Error:** Additive ("A") or multiplicative ("M")

#### **ETS models**

```
General notation ETS: ExponenTial Smoothing

∠ ↑ △

Error Trend Season
```

**Error:** Additive ("A") or multiplicative ("M")

**Trend:** None ("N"), additive ("A"), multiplicative ("M"), or damped ("Ad" or "Md").

## **ETS** models

```
General notation ETS: ExponenTial Smoothing

→ ↑ ►

Error Trend Season
```

**Error:** Additive ("A") or multiplicative ("M")

**Trend:** None ("N"), additive ("A"), multiplicative ("M"), or damped ("Ad" or "Md").

**Seasonality:** None ("N"), additive ("A") or multiplicative ("M")

## **ETS(A,N,N): SES with additive errors**

$$\hat{y}_{T+h|T} = \ell_T$$

$$y_t = \ell_{t-1} + \varepsilon_t$$

$$\ell_t = \ell_{t-1} + \alpha \varepsilon_t$$

where  $\varepsilon_t \sim \text{NID}(0, \sigma^2)$ .

## **ETS(A,N,N): SES with additive errors**

Forecast equation	$\hat{y}_{\mathcal{T}+h \mathcal{T}} = \ell_{\mathcal{T}}$
Measurement equation	$y_t = \ell_{t-1} + \varepsilon_t$
State equation	$\ell_t = \ell_{t-1} + \alpha \varepsilon_t$

where  $\varepsilon_t \sim \text{NID}(0, \sigma^2)$ .

- "innovations" or "single source of error" because equations have the same error process,  $\varepsilon_t$ .
- Measurement equation: relationship between observations and states.
- Transition/state equation(s): evolution of state(s) over time.

## ETS(M,N,N): SES with multiplicative errors

Forecast equation 
$$\hat{y}_{\mathcal{T}+h|\mathcal{T}} = \ell_{\mathcal{T}}$$
Measurement equation  $y_t = \ell_{t-1}(1+arepsilon_t)$ 
State equation  $\ell_t = \ell_{t-1}(1+lphaarepsilon_t)$ 

where  $\varepsilon_t \sim \text{NID}(0, \sigma^2)$ .

## ETS(M,N,N): SES with multiplicative errors

Forecast equation 
$$\hat{y}_{T+h|T} = \ell_T$$
Measurement equation  $y_t = \ell_{t-1}(1+\varepsilon_t)$ 
State equation  $\ell_t = \ell_{t-1}(1+\alpha\varepsilon_t)$ 

where  $\varepsilon_t \sim \text{NID}(0, \sigma^2)$ .

Models with additive and multiplicative errors with the same parameters generate the same point forecasts but different prediction intervals.

- 4 Seasonal methods
- 5 ETS taxonomy
- 6 Lab Session 15
- 7 Non-Gaussian forecast distributions

## **Lab Session 14**

Try forecasting the Chinese GDP from the global\_economy data set using an ETS model.

Experiment with the various options in the ETS() function to see how much the forecasts change with damped trend, or with a Box-Cox transformation. Try to develop an intuition of what each is doing to the forecasts.

[Hint: use h=20 when forecasting, so you can clearly see the differences between the various options when plotting the forecasts.]

## ETS(A,A,A): Holt-Winters additive method

Forecast equation  $\hat{y}_{t+h|t} = \ell_t + hb_t + s_{t+h-m(k+1)}$  Observation equation  $y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$  State equations  $\ell_t = \ell_{t-1} + b_{t-1} + \alpha \varepsilon_t$   $b_t = b_{t-1} + \beta \varepsilon_t$   $s_t = s_{t-m} + \gamma \varepsilon_t$ 

- $\mathbf{k} = \text{integer part of } (h-1)/m.$
- $\sum_i s_i \approx 0.$
- Parameters:  $0 \le \alpha \le 1$ ,  $0 \le \beta^* \le 1$ ,  $0 \le \gamma \le 1 \alpha$  and m = period of seasonality (e.g. m = 4 for quarterly data).

## ETS(M,A,M): Holt-Winters multiplicative method

Forecast equation  $\hat{y}_{t+h|t} = (\ell_t + hb_t)s_{t+h-m(k+1)}$ Observation equation  $y_t = (\ell_{t-1} + b_{t-1})s_{t-m}(1+arepsilon_t)$ State equations  $\ell_t = (\ell_{t-1} + b_{t-1})(1+lphaarepsilon_t)$   $b_t = b_{t-1}(1+etaarepsilon_t)$   $s_t = s_{t-m}(1+\gammaarepsilon_t)$ 

- k is integer part of (h-1)/m.
- Parameters:  $0 \le \alpha \le 1$ ,  $0 \le \beta^* \le 1$ ,  $0 \le \gamma \le 1 \alpha$  and m = period of seasonality (e.g. m = 4 for quarterly data).

### **Outline**

- 1 Exponential smoothing
- 2 Trend methods
- 3 Lab Session 14
- 4 Seasonal methods
- 5 ETS taxonomy
- 6 Lab Session 15
- 7 Non-Gaussian forecast distributions

# **Exponential smoothing models**

Additive Error		Seasonal Component		
	Trend	N	Α	M
	Component	(None)	(Additive)	(Multiplicative)
N	(None)	A,N,N	A,N,A	<u> </u>
Α	(Additive)	A,A,N	A,A,A	<u>^,^,M</u>
$A_d$	(Additive damped)	$A,A_d,N$	$A,A_d,A$	$\Delta_{\leftarrow}\Delta_{\leftarrow}M$

<b>Multiplicative Error</b>		Seasonal Component			
	Trend	N	Α	М	
	Component	(None)	(Additive)	(Multiplicative)	
Ν	(None)	M,N,N	M,N,A	M,N,M	
Α	(Additive)	M,A,N	M,A,A	M,A,M	
$A_d$	(Additive damped)	M,A <sub>d</sub> ,N	$M,A_d,A$	$M,A_d,M$	

## **Estimating ETS models**

- Smoothing parameters  $\alpha$ ,  $\beta$ ,  $\gamma$  and  $\phi$ , and the initial states  $\ell_0$ ,  $b_0$ ,  $s_0$ ,  $s_{-1}$ , ...,  $s_{-m+1}$  are estimated by maximising the "likelihood" = the probability of the data arising from the specified model.
- For models with additive errors equivalent to minimising SSE.
- For models with multiplicative errors, **not** equivalent to minimising SSE.

### **Model selection**

#### **Akaike's Information Criterion**

$$AIC = -2\log(L) + 2k$$

where *L* is the likelihood and *k* is the number of parameters & initial states estimated in the model.

### **Model selection**

#### **Akaike's Information Criterion**

$$AIC = -2\log(L) + 2k$$

where *L* is the likelihood and *k* is the number of parameters & initial states estimated in the model.

#### **Corrected AIC**

$$AIC_{c} = AIC + \frac{2k(k+1)}{T - k - 1}$$

which is the AIC corrected (for small sample bias).

### **Model selection**

#### **Akaike's Information Criterion**

$$AIC = -2\log(L) + 2k$$

where *L* is the likelihood and *k* is the number of parameters & initial states estimated in the model.

#### **Corrected AIC**

$$AIC_{c} = AIC + \frac{2k(k+1)}{T - k - 1}$$

which is the AIC corrected (for small sample bias).

#### **Bayesian Information Criterion**

$$\mathsf{BIC} = \mathsf{AIC} + k(\log(T) - 2).$$

### **AIC and cross-validation**

Minimizing the AIC assuming Gaussian residuals is asymptotically equivalent to minimizing one-step time series cross validation MSE.

## **Automatic forecasting**

#### From Hyndman et al. (IJF, 2002):

- Apply each model that is appropriate to the data. Optimize parameters and initial values using MLE.
- Select best method using AICc.
- Produce forecasts using best method.
- Obtain forecast intervals using underlying state space model.
  - Method performed very well in M3 competition.
  - Used as a benchmark in the M4 competition.

### **Outline**

- 4 Seasonal methods
- 5 ETS taxonomy
- 6 Lab Session 15
- 7 Non-Gaussian forecast distributions

### Lab Session 15

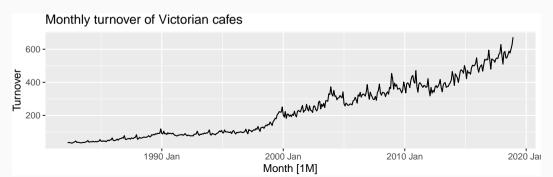

Find an ETS model for the Gas data from aus\_production.

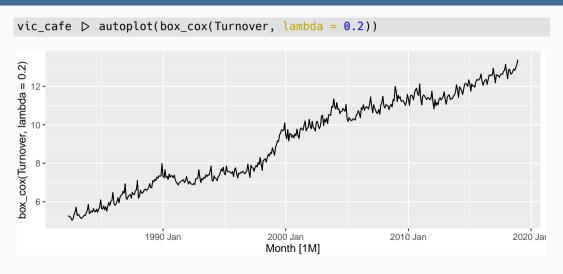

- Why is multiplicative seasonality necessary here?
- Experiment with making the trend damped. Does it improve the forecasts?

### **Outline**

- 1 Exponential smoothing
